**SEE Electrical V7 Crack \_\_HOT\_\_**

---

in august, 2011, shinbrot published his findings in the journal nature. in his experiment, he placed a thin sheet of paper or plastic in a tank filled with salt water. using a suction pump and a computer-controlled motor, he could move the sheet. he found that the grains under the paper were electrically charged, and that the pattern of the electrical charge changed as the sheet moved. the changes in the pattern of the electrical charge were the same as those in the wind tunnel. the discovery seemed to be a blow to the conventional theory that charges in sand were the cause of the effects. when the wind moves the sand, it forces the grains together, and they become electrically charged by the friction of the particles. when the sand is blown away by a suction pump, the grains remain apart, but are still electrically charged. and when the grains are placed in saltwater, they are attracted to the glass surface, which is conductive, and they repel each other. when the sheet is moving through the air, it has no surface to which the grains can attach. but, says shinbrot, the grains under the water are left with an electric charge. so when the sheet is in the water, the grains are electrically attracted to the glass, and the charge pattern changes. if the electrical signal were to be measured on a smaller scale, like at a laboratory-like scale, the impact of electrical signal might be clearer. its also possible that the tiny crack in the wire could be a factor in the signal. we do not know how the crack was made, whether it was made in the wire itself or if it came in from the outside. we know the crack has a diameter of a quarter to a third of the diameter of the wire, and we know it is conductive so that is what we are measuring with our electronic device. if the crack is very small, the electrical signal might not have the same effect it does in larger cracks.

---

## SEE Electrical V7 Crack

there might be other ways to try to find out if the crack can be detected before a slip occurs. shinbrots group might also find a way to attempt to control when the crack is created, or they might begin to work on ways to minimize any effect the crack has. once the signal is detected, its only a matter of time before the crack is noticed by someone on site. if the crack is large enough, it may be possible to try to anticipate the slip and reduce the damage, or at least warn people to avoid the area before the slip occurs. there might be a small increase in the rate of slip or a small shift in the location of the slip. with a few advanced sensors placed throughout the area, we might be able to tell whether the slip was activated there. it might be that the crack is a good location to place a sensor because the slip is initiated at a specific point and then travels there, or the location of the crack might affect the propagation of the slip. shinbrot was on the verge of publishing his first results when the media picked up the story of the electrical discharge from his tumbler. the story, with its accompanying pictures, was published in many newspapers. from this moment on, shinbrot says that the politicians finally started to pay attention to the results. before then, the political world was not interested in the application of dust. only after the media wrote that there was a mystery to be solved, that there was electrical communication from dust, that the dust had a secret code, and the scientists were trying to solve the mystery, that the politicians were interested. 5ec8ef588b
